This talk will present our on-going effort to control the dipole-dipole interaction between cold Rydberg atoms in order to implement spin Hamiltonians that may be useful for quantum simulation of condensed matter problems. In our experiment, we trap individual atoms in two-dimensional arrays of optical tweezers [Nogrette, Phys. Rev. X **4**, 021034 (2014)] separated by few micrometers and excite them to Rydberg states using lasers. The arrays are produced by a spatial light modulator, which shapes the dipole trap beam. We can create almost arbitrary, two-dimensional geometries of the arrays.

The talk will present our demonstration of the coherent energy exchange in small chains of Rydberg atoms resulting from their dipole-dipole interaction [Barredo, Phys. Rev. Lett. **114**, 113002 (2015)]. This exchange interaction realizes the XY spin model. We have also implemented the quantum Ising model [Labuhn, arXiv:1509.04543]. The spin $\frac{1}{2}$ Hamiltonian is mapped onto a system of Rydberg atoms excited by lasers and interacting by the van der Waals Rydberg interaction. We study various configurations such as one-dimensional chains of atoms with periodic boundary conditions, rings, or two-dimensional arrays containing up to 30 atoms. We measure the dynamics of the excitation for various strengths of the interactions between atoms. We compare the data with numerical simulations of this many-body system and found excellent agreement for some of the configurations.

This good control of an ensemble of interacting Rydberg atoms thus demonstrates a new promising platform for quantum simulation using neutral atoms, which is complementary to the other platforms based on ions, magnetic atoms or dipolar molecules.

Fluorescence images of individual atoms trapped in arrays of optical tweezers separated by a few micrometers

Dr. Antoine BROWAEYS

Senior Scientist (Directeur de Recherche), CNRS
Assistant Professor (Professeur Chargé de Cours), Ecole Polytechnique, Palaiseau, France
Leader of the “Quantum Optics – Atom” group, Laboratoire Charles Fabry, Institut d’Optique, France

Employment

2013 – ...	Directeur de Recherche, CNRS
2009 – ...	Maître de Conférence Ecole Polytechnique, Palaiseau, France
2003 – 2013	Chargé de Recherche, CNRS
2000 – 2003	Post-doctorant in Laser Cooling and Trapping group, NIST, USA

Education

1996 – 2000	PhD Institut d’Optique “Magnetic Trapping of Metastable He: towards Bose-Einstein Condensation”, Advisor: Alain Aspect.
--------------------	---

Awards

Aimé Cotton Prize of the French Physical Society (2007).
ERC Starting Grant Fellowship (2009-2014).
“La Recherche” Prize in Physics (2014).

Research interests

Experimental study of systems consisting of small number (1 - 100) of interacting, laser-cooled atoms. Quantum Optics; Quantum Physics; Manipulation of individual quantum systems; Many-body physics; Rydberg physics; Light scattering by dense atomic ensemble in the presence of light-induced dipole-dipole interactions.
